In the first place, the fact that, had we included A_0 in the assumed series there would have been no way of determining it, shows that $A_0 + (\sin^{-1}c)^2$ is a more general solution. Again, had the odd powers of x been included in the assumed series, there would have been no way of determining J_4 ; but the same relation (5) would have existed between the coefficients of successive odd powers. Thus we should have had the additional terms $A_j x^{--x} + + I^{-3-5+} 1V^{2.3} 2.3.4.5 2.3.4.5-6.7 /$ This last series is in fact that for $\sin^{-1} x$, and its occurrence is due to the fact that $y = \dots$
